PLEASE NOTE

The information contained in this publication is intended to provide a general guide to the characteristics and applications of these products. The material, herein, was developed through engineering design and development, testing and actual applications and is believed to be reliable and accurate.

However, Firestone makes no warranty, express or implied, of this information. Anyone making use of this material does so at his own risk and assumes all liability resulting from such use. It is suggested that competent professional assistance be employed for specific applications.

Firestone

World's Number 1 
Air Spring.

FIRESTONE INDUSTRIAL PRODUCTS COMPANY

HISTORY

In the early 1930's, the Firestone Tire and Rubber Company began experiments to develop the potential of pneumatic springs. In 1938, the country's largest manufacturer of motor coaches became interested in using air springs on a new design bus they were developing. Working with Firestone engineers, the first buses were tested in 1944 and the inherent ride superiority of air suspensions was clearly documented.

In the late 1940's, Firestone engineers, encouraged by the success of the bus application, turned their attention to the passenger rail market. They saw an opportunity to use an air spring in the secondary suspension of the rail truck or bogie. Working closely with rail truck manufacturers, the engineers at Firestone were able to perfect the double convoluted style of air spring for rail applications; consequently, this style became the standard for the next several years.

Development continued into other vehicular applications.

Firestone made huge in-roads into the automotive, heavy truck and trailer markets.

With the invention of the reversible style air spring, significant improvements were made to the performance of the air springs in these applications. Eventually the passenger rail car manufacturers desired the benefits of the reversible style air spring as well. Continuing in the spirit of joint development, Firestone worked with rail truck engineers to perfect and finalize a reversible style air spring system for rail applications.

Firestone Industrial Products continues to supply and develop convoluted and reversible style air springs to passenger rail markets all over the world.

ADVANTAGES

Passenger Comfort

Suspension systems designed with Airail™ springs provide a uniformly smooth ride for passenger comfort. The rail car is cushioned by air springs from the jolts and vibration experienced by the rail truck. By incorporating an auxiliary air reservoir, the frequency and spring rate characteristics of the air spring can be modified to the exact specifications of the suspension designer. Utilizing Firestone's extensive computer modeling programs, the effect of orifice damping can be determined for controlled shock absorption.

Constant Floor Height

With the use of a leveling system, the air springs can be used to keep the car floor at a constant height. When passengers enter, exit or change positions in the rail car, the air springs and leveling system are used to maintain a level floor during operation and at station platforms to insure passenger safety and comfort.

Performance Benefits

Due to the overall construction, air springs are virtually noise free and therefore are able to meet the demands of rail operators for noise reduction.

Another added benefit is a proven service life. Airail™ springs are constructed of highly engineered materials to reduce the effects of abrasion, heat build-up and ozone attack, making them capable of service life up to and exceeding ten years.

TERMS – AIR SPRINGS & SUSPENSIONS

PRESSURE & PROCESS TERMS

Absolute Pressure. The pressure in a vessel located in a complete vacuum. Usually determined by adding 14.7 pounds per square inch (psi) to the gauge pressure. Absolute pressure=gauge pressure+atmospheric pressure.

Adiabatic Process. All the calculation variables (volume, pressure, and temperature), change without any heat transfer (not often a real life situation).

Atmospheric Pressure. The average atmospheric air pressure measured at sea level. Normally accepted to be 14.7 pounds per square inch (psi).

Constant Volume With Airflow Process. Volume and temperature constant, pressure changes. This condition applies when load is added or removed from above the air spring over a period of time.

Gauge Pressure. Gas or liquid pressure in a vessel, which is higher than atmospheric pressure. Usually measured by a Bourdon tube gauge in pounds per square inch (psi).

Polytropic Process. All the calculation variables (volume, pressure, and temperature), change with heat transfer to the air spring structure. To account for this, air spring dynamic operation is calculated by the use of what is known as the polytropic exponent (n). $n=1.38$ is the generally accepted value for air springs.

AIR SPRING COMPONENT TERMS

Bead. A part of the flexible member that locks the cord structure to an inside reinforcing metal ring and provides a means of sealing the joint between the flexible member and the adjacent structure.

Bead Plate. A metal plate closing the top end of the flexible member. It is attached to the flexible member with a clamp ring. It has studs, blind nuts, brackets, or pins to facilitate its attachment to the vehicle structure. A means of supplying air to the assembly is provided as a separate fitting or in combination with an attachment stud. Convoluted type springs incorporate a second bead plate on the bottom to create an air tight unit and to provide a means of fastening the unit to the suspension.

Bead Ring. A metal ring incorporating a shaped cross-section that grips the bead of the flexible member and provides a means of attaching and sealing the bead to a plate or other structure.

Bead Skirt. A bead ring (see above description) that has a profile such that it controls the lateral movement of the spring. A bead skirt is used in reversible style air springs to give specific lateral spring rates as required by the car manufacturer.

Bumper. Usually, these are made of rubber, rubber and fabric, or steel and rubber materials. They are used to support the vehicle when there is no air in the air springs, when the vehicle is not in use, or when there is a system failure on the track. They will also, to some degree, cushion the shock of very severe axle force inputs to prevent damage to both the Airrail™ spring assembly and to the vehicle.

Clamp Ring. A metal hoop that is used to secure a bead plate to the flexible member.

Flexible Member. The fabric-reinforced rubber component of the air spring assembly or component of the air spring.

Piston. A metal component of the air spring assembly usually placed at the lower end of the flexible member and used to both support and provide a surface for the flexible member to roll on. It also provides a means for attaching the assembly to the mounting surface. Pistons with tailored contours may be used to obtain air spring characteristics to meet special performance requirements.

AIR SPRING TERMS

Assembly. This includes the flexible member, which may include an upper bead plate, piston, or lower bead plate with an internal bumper. See illustration on pages 7-9.

Assembly Volume. The internal working air volume, exclusive of any external working volume.

Bumper Volume. The space taken up inside the air spring assembly by the bumper.

Compression Stroke (Jounce). The reduction in height from the normal design height of the spring as it cycles in dynamic operation.

Design Load. This is the normal maximum static load the air spring suspension is expected to support. It is the rated axle load divided by the number of air springs working with the axle and adjusted according to any suspension lever arm ratio incorporated.

Design Height. The overall height of the air spring as selected from the characteristics chart design position range. The air spring selected should provide for adequate jounce and rebound travel for the proposed suspension. The design height would be the starting position for calculating the spring and suspension dynamic characteristics.

Dynamic Force. The instantaneous supporting force developed by the air spring during vehicle motion. It is this constantly changing force that creates the spring rate, suspension rate, and in combination with the normal vehicle load on the spring, creates the suspension system's natural frequency.

Effective Area. The actual working area perpendicular to the output force of the spring. It is not the diameter of the spring. This working area, when multiplied by the gauge pressure in the spring, produces the correct output force. Conversely, dividing the measured output force of the spring by the measured internal gauge pressure obtains the correct effective area. In many cases, this is the only practical way to obtain it.

Extension Stroke (Rebound). The increase in height from the normal design height of the spring as it cycles in dynamic operation.

Reservoir Volume. Any working air volume located externally from the air spring assembly, but functioning with the spring.

SUSPENSION RELATED TERMS

Height Sensor. An electronic device that senses the position of a suspension or other mechanical device. The output signal from this device is sent to a control circuit which then exhausts or adds air to the air spring through a solenoid valve.

Leveling Valve. A pneumatic valve that senses the distance between the vehicle frame and the axle via a mechanical linkage which adds or exhausts air pressure to maintain a constant vehicle height.

Sprung Mass Natural Frequency. The speed of vertical oscillations of the suspended vehicle sprung mass. Can be expressed in cycles per minute (cpm) or cycles per second (hertz).

Sprung Mass (Weight). That part of the vehicle structure and cargo that is supported by the suspension.

Unsprung Mass. That part of the suspension that is not supported by the spring (e.g., axle wheels, air spring, etc.).

CONSTRUCTION OF AIR SPRINGS

FLEXIBLE MEMBER CONSTRUCTION

An air spring is a carefully designed rubber and fabric flexible member which contains a column of compressed air. The flexible member itself does not provide force or support load; these functions are performed by the column of air.

Firestone air springs are highly engineered elastomeric flexible members with specifically designed metal end closures. The two-ply version is made up of four layers:

- **Inner Liner.** An inner liner of calendered rubber.
- **First Ply.** One ply of fabric-reinforced rubber with the cords at a specific bias angle.
- **Second Ply.** A second ply of fabric-reinforced rubber with the same bias angle laid opposite that of the first ply.
- **Outer Cover.** An outer cover of calendered rubber.

Although the two-ply air spring is available, most Firestone air springs for rail applications are built with four-ply rated construction.

Each air spring's flexible member is identified by a style number, which is molded-in during the curing (vulcanization) process. Examples would be 29, 218, 1T60, etc. This identifies only the rubber/fabric flexible member . . . not the complete assembly.

STYLES OF AIR SPRINGS

REVERSIBLE STYLE AIR SPRING WITH BEAD SKIRT

- A Bead Plate.** A metal component, typically steel, plated for corrosion resistance, bolted to the bead skirt to create an airtight assembly that allows for leak testing before the unit leaves the factory.
- B Bead Skirt.** A metal component, typically aluminum, plated for corrosion resistance that is used to attach the flexible member to the bead plate and also to control the lateral movement of the spring.

- C Flexible Member.** See page 6 for flexible member construction information.
- D Piston.** A metal component, typically aluminum, plated for corrosion resistance whose profile, along with the bead skirt, can further influence the vertical and lateral characteristics of the spring per the designer's requirements.
- E Bumper.** An internal component made of rubber, rubber and fabric or rubber and steel that is used to prevent damage to the air spring or rail car during times when no air is in the system.

Firestone

CONVOLUTED AIR SPRINGS – ROLLED PLATE ASSEMBLIES

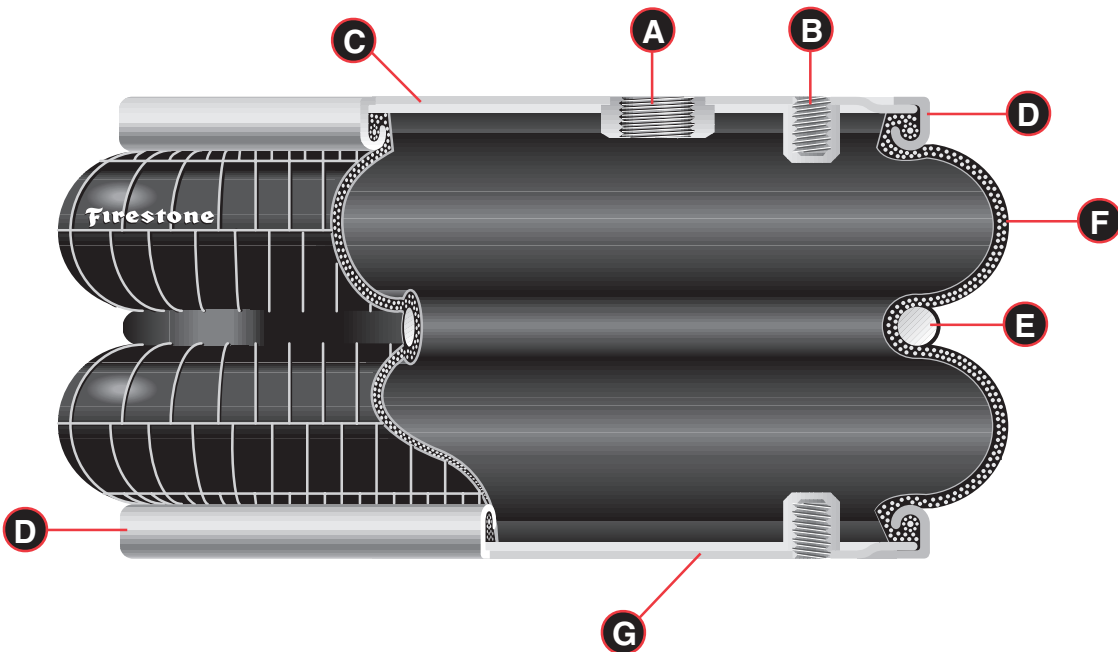

Convoluted parts are available with bead rings or permanently attached plates called “rolled plates.” Rolled plate assemblies may offer an advantage over bead ring parts because installation is much easier.

When installing rolled plate parts, a backup plate, as large in diameter as the bead plate, must be used. This plate should be a minimum of .50” thick.

The blind nut and air entrance locations of rolled plate assemblies are available from Firestone.

- A Air Inlet.** 3/4” NPT is standard.
- B Blind Nut.** 1/2”-13 UNC thread x .75” deep. Studs or pins can be used in place of blind nuts.

- C Upper Bead Plate.** 6-gauge (.194”) carbon steel, plated for corrosion resistance. Permanently attached to the flexible member with a clamp ring (D) to form an airtight assembly. Allows for leak testing before the assembly leaves the factory.
- D Clamp Ring.** This ring is crimped to the bead plate to permanently attach it to the flexible member. It is also plated for rust protection.
- E Girdle Hoop.** Solid type shown, molded into the flexible member between the convolutions.
- F Flexible Member.** See page 6 for flexible member construction information.
- G Lower Bead Plate.** Usually the same as the upper bead plate, except without the air inlet.

CONVOLUTED AIR SPRINGS – BEAD RING ASSEMBLIES

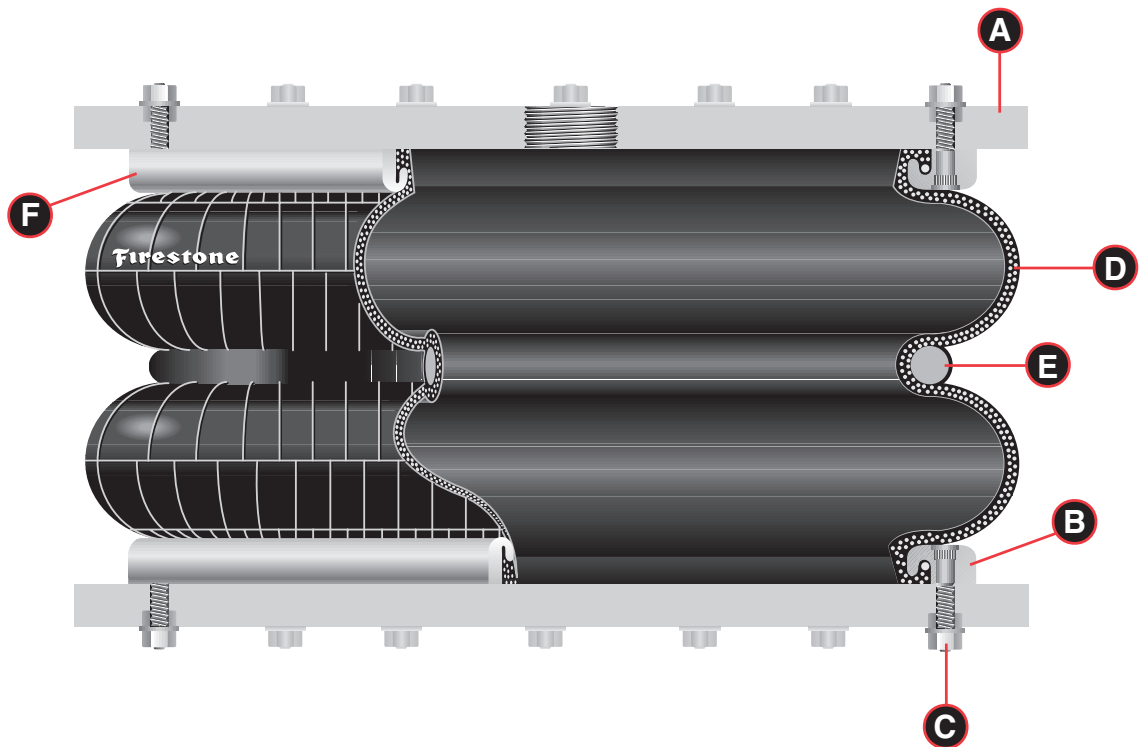

- A Mounting Plate.** Not included. See page 10 for material, machining recommendations and installation instructions.
- B Bead Ring Bolt.** Some assemblies may include one of three varieties included with air spring assemblies. See chart on page 10.
- C Nuts & Lock Washers.** Included with air spring assembly.
- D Flexible Member.** See page 6 for flexible member construction information.
- E Girdle Hoop.** Solid type shown, molded into the flexible member, between the convolutions.

- F Bead Ring.** Aluminum ribbed neck type shown. May also be of a second stamped steel variety or made of aluminum (see page 10).

SERVICE ASSEMBLY

The flexible member is available separately as a replacement on convoluted bead ring assemblies.

Note: No convoluted bead ring assemblies are shown in the following product data sheets. All convoluted air springs shown are available in bead ring assemblies.

BEAD RINGS

THREE TYPES OF BEAD RINGS

STEEL COUNTERSUNK BEAD RING	ALUMINUM RIBBED NECK BEAD RING	ALUMINUM SOCKET HEAD BEAD RING*
Standard Bolt Length (in) 1%	Standard Bolt Length (in) 1%	Standard Bolt Length (in) 1 1/4
Standard Effective Length (in) 1.22	Standard Effective Length (in) 1.28	Optional Effective Length (in) 0.66
Standard Order Number (bolt only) WC1-358-3625	Standard Order Number (bolt only) WC1-358-3620	Optional Order Number (bolt only) WC1-358-3618
Thread 5/16-24UNF	Thread 3/8-24UNF	Thread 3/8-24UNF
Tightening Torque (ft-lb) 17 to 22	Tightening Torque (ft-lb) 28 to 32	Tightening Torque (ft-lb) 28 to 32

INSTALLING AIR SPRINGS WITH BEAD RINGS

When using bead rings, you will need to fabricate your own mounting plates. Hot or cold rolled steel provides satisfactory mounting surfaces with finishes of 250 micro inches, if machined in a circular fashion, or 32 micro inches when ground (side-to-side). The thickness of mounting plates depends upon the application. The plates must be strong enough and backed by structural members to prevent bowing of the plates when subjected to the forces or loads involved. The flexible member provides its own seal, so "O" rings or other sealants are not required.

INSTALLATION

Follow this technique for assembling a bead ring style flexible member to the mounting plate:

1. Insert the bolts into the bead ring, which has already been attached to the flexible member.
2. Slip all of the bolts, which protrude through the bead ring, into the mating holes of the mounting plate and attach the lock washers and nuts. Finger

tighten all nuts to produce a uniform gap between the bead ring and mounting plate all the way around. The bolts will be pulled into place by the action of tightening the nuts. When using *aluminum* bead rings, it may be necessary to lightly tap the ribbed neck bolts with a small hammer to engage the splined portion into the bead ring.

3. Make certain that the flexible member bead is properly seated under the bead ring. *Please note that uniform successive tightening of the nuts is important to seat the rubber bead properly to the mounting plate around its full circumference.*
4. Tighten all nuts one turn each, moving around the circle until continuous contact is made between the bead ring and mounting plate.
5. Torque all nuts to the torque specifications shown in the chart above, going at least two complete turns around the bolt circle.

Note: Consult Firestone for proper selection of bead ring type.

HOW TO USE THE PRODUCT DATA SHEETS

INTRODUCTION

This section is a guide to using the Product Data Sheets which Firestone Industrial Products Company publishes for Airail™ air springs.

These sheets show the mounting configuration, physical limitations and technical characteristics of the air spring. With this information, the suspension designer can accurately calculate the overall performance of an air suspension system.

The Product Data Sheets can also serve as a guide for selecting a particular air spring for a new suspension system.

- A** The part description is shown in the upper right corner.
- B** Bead plate diameter.
- C** Bead plate mounting arrangement.
- D** Bead skirt diameter, or on convoluted air spring data sheets, the maximum rubber part diameter at 100 psig and minimum height.
- E** Piston body diameter.
- F** Bumper.
- G** "B" dimension. The distance from the piston base mounting surface to the bottom of the loop of the flexible member.
- H** The assembly Order Number, W01-358-9456.
- I** Approximate weight of the assembly.

STATIC DATA CHART

This chart is referred to as the *Static Load Deflection Curve* for an air spring. The following parameters are displayed:

- A Recommended Design Position Static Pressure.** The recommended static operating pressure range is shown at the top of the chart. This is 20 to 100 psig for most air springs. The minimum pressure is required to prevent internal damage to the air spring.
- B The Load** is given on the right-hand axis vs. the air spring **Height** along the bottom axis. The internal **Volume** is also given along the left-hand axis vs. the **Height**.
- C The Bumper Contact** shows the compressed height of the air spring when the bead plate comes in contact with the internal bumper as shown on the air spring drawing.
- D The Minimum Height** shows the lowest compressed position of the air spring before internal contact. In many instances, an external positive stop may be required to prevent internal damage to the air spring.
- E The Maximum Rebound Height** is the maximum extended position of the air spring before the flexible member is put in tension. Some means of preventing the suspension extending the air spring past this height must be provided to prevent damage to the air spring. Shock absorbers are typically used, however chains, straps, and positive stops may also be used.
- F The Design Position Range** shows the recommended operating range of static heights. This range is 8 to 10 inches for the 1T52-420, as shown on the chart. Use outside range may be possible, however, Firestone should be consulted.
- G The Constant Pressure Curve** is the Load trace obtained as the part is compressed from the maximum height to the minimum height while maintaining a regulated constant pressure in the part. A series of constant pressure curves, 20 psig through 120 psig are shown at 20 psi increments. The 120 psig curve is shown for reference only, as most parts are limited to static design pressure of 100 psig.

(continued on page 13)

STATIC DATA CHART (continued)

- H** The **Volume Curve** is a plot of the data points obtained by measuring the volume of exhausted liquid as the part is compressed from maximum to minimum height while maintaining a regulated pressure of 100 psig in the air spring. (This is the volume without a bumper).
- I** The number, 6773, is the **Test Request Reference Number**.

100 PSIG DATA TABLE

This is a table of static data on the 100 psig constant pressure curve with loads, volumes and “B” dimensions shown.

The Static Data Table contains the following information:

- Height at each .50" increment.
- Load at each .50" increment.
- Volume at each .50" increment.
- “B” dimension (the distance from the piston base mounting surface to the bottom of the loop of the flexible member) at each .50" increment.

All data is calculated without a bumper.

100 Psig Data			
Height (in)	Load (lbs)	Volume (in³)	B Dim. (in)
17.00	30715	4263.80	
16.50	31183	4109.72	7.32
16.00	31666	3951.81	7.04
15.50	32062	3790.89	6.79
15.00	32317	3627.78	6.46
14.50	32412	3463.29	6.15

DYNAMIC CHARACTERISTICS TABLE

The Dynamic Characteristics Table consists of the following calculated characteristics:

- Data for three design heights within the design position range: minimum, midrange and maximum.
- Four loads at each design height.
- Pressure, Rate, and Frequency for each design height and load condition.

All data is calculated without a bumper.

RATE AND FREQUENCY WITH INCREASING VOLUME

This chart shows the change in the air spring's vertical rate and natural frequency with the addition of external reservoir volume.

The data is calculated at a mid-range design height and at 100 psig internal volume.

All data is calculated without a bumper.

Dynamic Characteristic at Various Design Heights					
Design Height (in)	Load (lbs)	Pressure (psig)	Rate (lbs/in)	Natural Frequency	
				(CPM)	(Hz)
8.00	14000	38.0	3323	91.6	1.53
8.00	22000	59.8	4584	85.8	1.43
8.00	30000	81.5	5844	83.0	1.38
8.00	38000	103.2	7104	91.3	1.35
9.00	14000	36.8	3402	92.7	1.54
9.00	22000	57.8	4751	87.4	1.46
9.00	30000	78.8	6101	84.8	1.41
9.00	38000	99.9	7450	83.2	1.39
10.00	14000	36.6	3315	91.5	1.52
10.00	22000	57.5	4672	86.6	1.44
10.00	30000	78.4	6028	84.3	1.40
10.00	38000	99.3	7385	82.9	1.38

Rate and Frequency with Increasing Volume at 9" Design Height and 100 psi			
Reservoir Volume (in³)	Vertical Rate (lbs/in)	Vertical Natural Frequency	
		(CPM)	(Hz)
0	7480.00	83.4	1.39
1500	4639.65	65.7	1.09
3000	3275.75	55.2	0.92
4500	2470.51	47.9	0.80
6000	1938.87	42.4	0.71

5773

DYNAMIC LOAD VS. DEFLECTION CHART

This chart shows the variation in **Dynamic Load vs. Deflection** for the 1T52-420.

The curves are obtained by extending (rebound) or compressing (jounce) the air spring with captured air.

The *starting* point for each curve is at a design height of 9 inches, which is the mid-design position, and *starting* pressures of 20, 40, 60, 80 and 100 psig.

As you can see on the DYNAMIC LOAD axis, the load is approximately 38,000 lb at the design height of 9 inches and pressure of 100 psig.

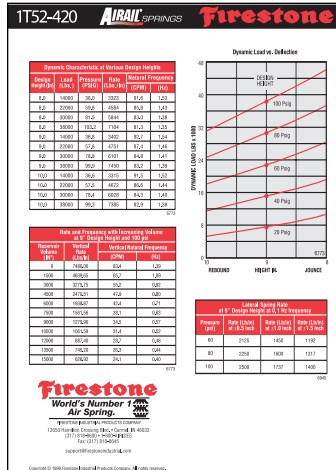

When the air spring is compressed one inch to an 8 inch height, the load increases to approximately 46,000 lb, (with a corresponding increase in pressure to 125 psig).

When the air spring is extended one inch to a 10 inch height, the load is reduced to 31,000 lb, (with a corresponding reduction in pressure to 78 psig).

LATERAL SPRING RATE

This chart shows the calculated lateral spring rate of the air spring.

The lateral rates are calculated at a mid-range design height and an input frequency of 0.1 Hz.

Lateral Spring Rate at 9" Design Height & 0.1 Hz frequency			
Pressure (psi)	Rate (lbs/in) at ± 0.5 in	Rate (lbs/in) at ± 1.0 in	Rate (lbs/in) at ± 1.5 in
60	2125	1450	1192
80	2250	1600	1317
100	2500	1737	1400

6945

FASTENER TIGHTENING SPECIFICATIONS

Description	Size	Torque (ft-lb)
• Bead ring nuts on bolts	$\frac{5}{16}$ -24	17-22
• Bead ring bolts and nuts	$\frac{3}{8}$ -24	28-32
• Bolts in blind nuts in bead plates	$\frac{3}{8}$ -16	15-20
• End of adapter studs in blind nut	$\frac{3}{8}$ -16	15-20

• Studs on bead plates or blind nuts	$\frac{1}{2}$ -13 or $\frac{1}{2}$ -20	25-30
• Bolt to attach piston base to lower mounting surface	$\frac{1}{2}$ -13	25-30
• Nut on air entrance stud	$\frac{3}{4}$ -16	40-45
• NPT air supply fitting	$\frac{1}{4}$ & up	17-22
• Nut on end closure lower mounting	$\frac{3}{4}$ -10	45-50

OPERATIONAL CAUTIONS

Air spring failure can be caused by a variety of situations, including internal or external rubbing, excessive heat and overextension.

TEMPERATURE RANGE

The normal ambient operating temperature range for standard vehicular air springs is -65°F to +135°F.

BUMPERS

In general, bumpers are used to support the vehicle weight to prevent damage to the flexible member during times when no air is in the system. In applications that require frequent bumper contact, consult Firestone. There are a variety of bumpers available for use in Airrail™ springs. Firestone has developed a line of progressive springs under the trade name Marsh Mellow™. These springs have been used extensively in rail springs because of their unique performance characteristics. Due to the Marsh Mellow™ spring's greater deflection capabilities and load carrying influences of the fabric reinforcement, it can carry a greater load when compared to an all rubber part of the same modulus and dimensions.

Firestone also offers molded rubber bumpers that are manufactured by Firestone along with the Marsh Mellow™ springs, if required bumpers can be purchased from outside vendors for use inside the Airrail™ springs.

INTRODUCTION

The fundamental concept of an air spring is a mass of air under pressure in a vessel arranged so that the pressure exerts a force. The amount of static force developed by the air spring is dependent on the internal pressure and the size and configuration of the vessel. The vessel is defined in this manual as the Airrail™ spring by Firestone or air spring.

Dynamic force is the result of internal pressure changes and air spring effective area changes as height decreases (compresses) or increases (extends).

The amount of pressure change for a stroke depends on volume change compared to total volume at equilibrium position. For the convoluted type, effective area change for a stroke depends on where in the total travel range the motion takes place. For the reversible sleeve type, the shape of the piston, size of the piston related to the flexible member diameter, and cord angle built into the flexible member all have an influence on effective area.

The effective area can be arrived at by taking the longitudinal static force developed at a specified assembly height and dividing this force by the internal pressure (psig) existing in the air spring at that height. This method is used to develop the static effective areas used in dynamic rate and frequency calculations.

EFFECTIVE AREA

Effective area is the load carrying area of the air spring. Its diameter is determined by the distance between the centers of the radius of curvature of the flexible member loop. The loop always approximates a circle because the internal air pressure is acting uniformly in all directions, so that only the area inside the centers is vertically effective. For a convoluted air spring, the effective area increases in compression and decreases on extension. For a reversible sleeve air spring, the effective area is constant while operating on the straight side of the piston, increases when working on the flare of the piston in compression, and decreases when the rubber part lifts off the piston in extension.

When a vehicle having air springs in its suspension is at rest, and then load is added or removed, the height control valve operates to add or remove sufficient air in the air spring to maintain the set air spring overall height. This then increases or decreases the pressure in the air spring the amount needed to provide the required lifting force to match the current downward force created by the new load condition, and equilibrium is again reached.

SPECIAL CHANGES OF STATE FOR IDEAL GASES

Non-flow process, specific heats assumed constant. Subscripts 1 and 2 refer to the initial and final states, respectively.

P = Absolute Pressure
T = Absolute Temperature
V = Total Volume

1 Constant Volume (Isochoric)

$$\frac{P_2}{P_1} = \frac{T_2}{T_1}$$

This is an unattainable process due to the nature of the flexible member; however, at static conditions, the change in pressure may be calculated for a change in temperature.

2 Constant Pressure (Isobaric)

$$\frac{V_2}{V_1} = \frac{T_2}{T_1}$$

Dynamically, the only way to maintain constant pressure is in combination with infinite volume and is generally not useful.

3 Constant Temperature (Isothermal)

$$\frac{P_2}{P_1} = \frac{V_2}{V_1}$$

This requires very slow movements not normally applicable to air spring operation.

4 Reversible Adiabatic (Isentropic)

$$P_1 V_1^k = P_2 V_2^k$$

And:

$$\frac{T_2}{T_1} = \left(\frac{V_2}{V_1}\right)^{k-1} = \left(\frac{P_2}{P_1}\right)^{\frac{(k-1)}{k}}$$

This is defined as a process with no heat transferred to or from the working fluid. This is a

theoretical process not attainable with pneumatic springs, however, for rapid deflections, it is closely approached. $k=1.404$ for air.

5 Polytropic

$$PV^n = \text{Constant}$$

This process usually represents actual expansion and compression curves for pressures up to a few hundred pounds. Assuming the specific heat of the gas is constant, "n" may be changed for special cases of the polytropic process.

Thus for:

$n = 1$, $PV = \text{Const.}$ (Isothermal)
 $n = k$, $PV^k = \text{Const.}$ (Isentropic)
 $n = 0$, $P = \text{Const.}$ (Constant Pressure)
 $n = \infty$, $V = \text{Const.}$ (Constant Volume)

The principal formulas for air compression up to a few hundred pounds pressure where $1 < n < k$ are:

6 Reversible Adiabatic (Isentropic)

$$P_1 V_1^n = P_2 V_2^n$$

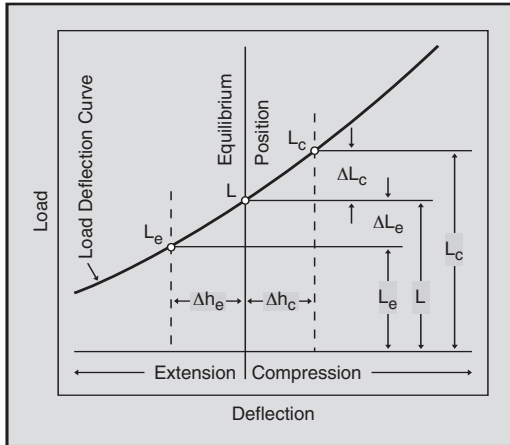

And:

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{n-1} = \left(\frac{P_2}{P_1}\right)^{\frac{(n-1)}{n}}$$

During air spring dynamic operation, the pressure, volume and temperature change instantaneously. The air spring flexible member structure also changes depending upon the specific configuration. As a result, air springs operate in the range $1 < n < k$, however, a generally acceptable value for "n" is 1.38 for normal vehicle operation.

Note: Red boxes are used to designate important formulas.

DYNAMIC AIR SPRING RATE

Rate is the slope of the tangent at the equilibrium position. For small increments of deflection, rate equals the load change per unit deflection.

(The slope of the chord line through L_c and L_e is parallel to the tangent at L for small deflections.)

$$\boxed{1} \quad K = (L_c - L_e) / (\Delta h_c + \Delta h_e)$$

Where:

K = Rate (Load per unit deflection)

L_c = Load at compression travel

L_e = Load at extension travel

Δh_c = Height change, compression

Δh_e = Height change, extension

$$\boxed{2} \quad L_c = P_{gc}(A_c) \\ L_e = P_{ge}(A_e)$$

Where:

P_{gc} = Gauge Pressure at L_c

P_{ge} = Gauge Pressure at L_e

A_c = Effective area at L_c

A_e = Effective area at L_e

substituting $\boxed{2}$ in $\boxed{1}$ and setting $\Delta h_c = \Delta h_e = .5$ inch

$$\boxed{3} \quad K = P_{gc}(A_c) - P_{ge}(A_e)$$

$$\boxed{4} \quad P_{gc} = P_{ac} - 14.7 \\ P_{ge} = P_{ae} - 14.7$$

Where:

P_{ac} = Absolute Pressure at L_c

P_{ae} = Absolute Pressure at L_e

14.7 = Atmospheric Pressure in pounds per in²

$$\boxed{5} \quad \text{Now using the polytropic gas law and } n=1.38$$

$$P_{ac} = P_{a1} \left(\frac{V_1}{V_c} \right)^{1.38}$$

$$P_{ae} = P_{a1} \left(\frac{V_1}{V_e} \right)^{1.38}$$

Where:

P_{a1} = Absolute Pressure at equilibrium position

V_1 = Volume at equilibrium position

V_c = Volume at L_c

V_e = Volume at L_e

substituting $\boxed{5}$ in $\boxed{4}$

$$\boxed{6} \quad P_{gc} = P_{a1} \left(\frac{V_1}{V_c} \right)^{1.38} - 14.7$$

$$P_{ge} = P_{a1} \left(\frac{V_1}{V_e} \right)^{1.38} - 14.7$$

substituting $\boxed{6}$ in $\boxed{3}$

$$\boxed{3} \quad K = P_{gc}(A_c) - P_{ge}(A_e)$$

$$\boxed{7} \quad K = \left[P_{a1} \left(\frac{V_1}{V_c} \right)^{1.38} - 14.7 \right] A_c - \left[P_{a1} \left(\frac{V_1}{V_e} \right)^{1.38} - 14.7 \right] A_e$$

Then, grouping terms, this becomes the general rate formula for air springs.

$$\boxed{8} \quad K = P_{a1} \left[A_c \left(\frac{V_1}{V_c} \right)^{1.38} - A_e \left(\frac{V_1}{V_e} \right)^{1.38} \right] - 14.7(A_c - A_e)$$

NATURAL FREQUENCY

Since the air spring has a variable rate and essentially a constant frequency, it is helpful to calculate the natural frequency when evaluating characteristics.

When considering a single-degree-of-freedom system (undamped), the classical definition of frequency is as follows:

Note: The period of free vibration (which is the reciprocal of frequency) is the same as the period of a mathematical pendulum, the length of which is equal to the static deflection of the spring under the action of load W.

$$f = \frac{\omega}{2\pi} \text{ and } \omega^2 = \frac{K}{m}$$

Where:

- f = Frequency, cycles per second
- ω = Circular frequency, radians per second
- K = Rate, pounds per inch
- m = Mass, pound seconds² per inch

Then:

$$f = \frac{\sqrt{K}}{2\pi} = \frac{1}{2\pi} \sqrt{\frac{K}{m}}$$

Also:

$$m = \frac{W}{g}$$

Where:

- W = Weight, pounds
- g = Acceleration of gravity, 386 inches per second²

Substituting:

$$f = \frac{1}{2\pi} \sqrt{\frac{Kg}{W}} = \frac{\sqrt{386}}{2\pi} \sqrt{\frac{K}{W}} \text{ cps}$$

$$f = \frac{60 \sqrt{386}}{2\pi} \sqrt{\frac{K}{W}} \text{ cpm}$$

This is normally rounded to:

$$f = 188 \sqrt{\frac{K}{W}} \text{ cpm}$$

Where:

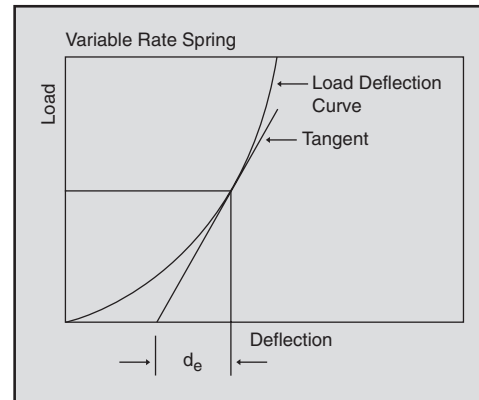

- K = Rate
- W = Weight (load)

Also since:

$$\frac{W}{K} = d_e \text{ (effective deflection)}$$

$$f = \frac{188}{\sqrt{d_e}} \text{ cpm}$$

Effective deflection (d_e) has no physical significance, however, it has mathematical meaning. It is defined as load divided by rate and is graphically explained below.

$$d_e = \frac{\text{Load}}{\text{Rate}}$$

$$\text{Load} = \text{Rate} \times d_e$$

Note: For a constant rate spring, d_e and the deflection from free height are equal.

SUMMARY OF IMPORTANT FORMULAS

Polytropic Gas Law

$$P_1 V_1^n = P_2 V_2^n$$

Dynamic Air Spring Rate

$$K = P_{a1} \left[A_c \left(\frac{V_1}{V_c} \right)^{1.38} - A_e \left(\frac{V_1}{V_e} \right)^{1.38} \right] - 14.7(A_c - A_e)$$

Natural Frequency

$$f = 188 \sqrt{\frac{K}{W}} = \frac{188}{\sqrt{d_e}} \text{ cpm}$$
